

Identifying Snow with Daytime RGB Satellite Products

Bernie Connell

Cooperative Institute for Research in the Atmosphere
Colorado State University

How can snow be determined from
day-time multispectral imagery?
AND
How many different RGB combinations
are available?

Why are there different techniques?

- Purpose of product:
 - To discriminate snow
 - To distinguish something else (ie clouds); snow was a (bonus) bi-product
- Not an easy solution:
 - Different developers, different ideas, different visual capabilities
- Algorithm mask for input to models or GFE **VS.** contextual visualization
- Different sensors, different channels available

Which one(s) have you seen?

Polar Orbiting (MODIS and VIIRS) based

- CIRA / Naval Research Laboratory (NRL)
Cloud Layers & Snow Cover Discriminator
- SPoRT / NASA Rapid Response / CIMSS
False Color Snow
- CIMSS / NASA Rapid Response
False Color (similar to EU Natural Color)

GOES and SEVERI based

- CIRA – Snow / Cloud Discriminator
- EUMETSAT – Natural Color

Notes...

- RGB imagery is being promoted by the GOES-R and JPSS Proving Grounds to help interpret multi-channel information
- The presenter does not know of an "officially designated" snow RGB
- RGB imagery cannot currently be created in AWIPS I
- Creation of RGB imagery in AWIPS II is a goal

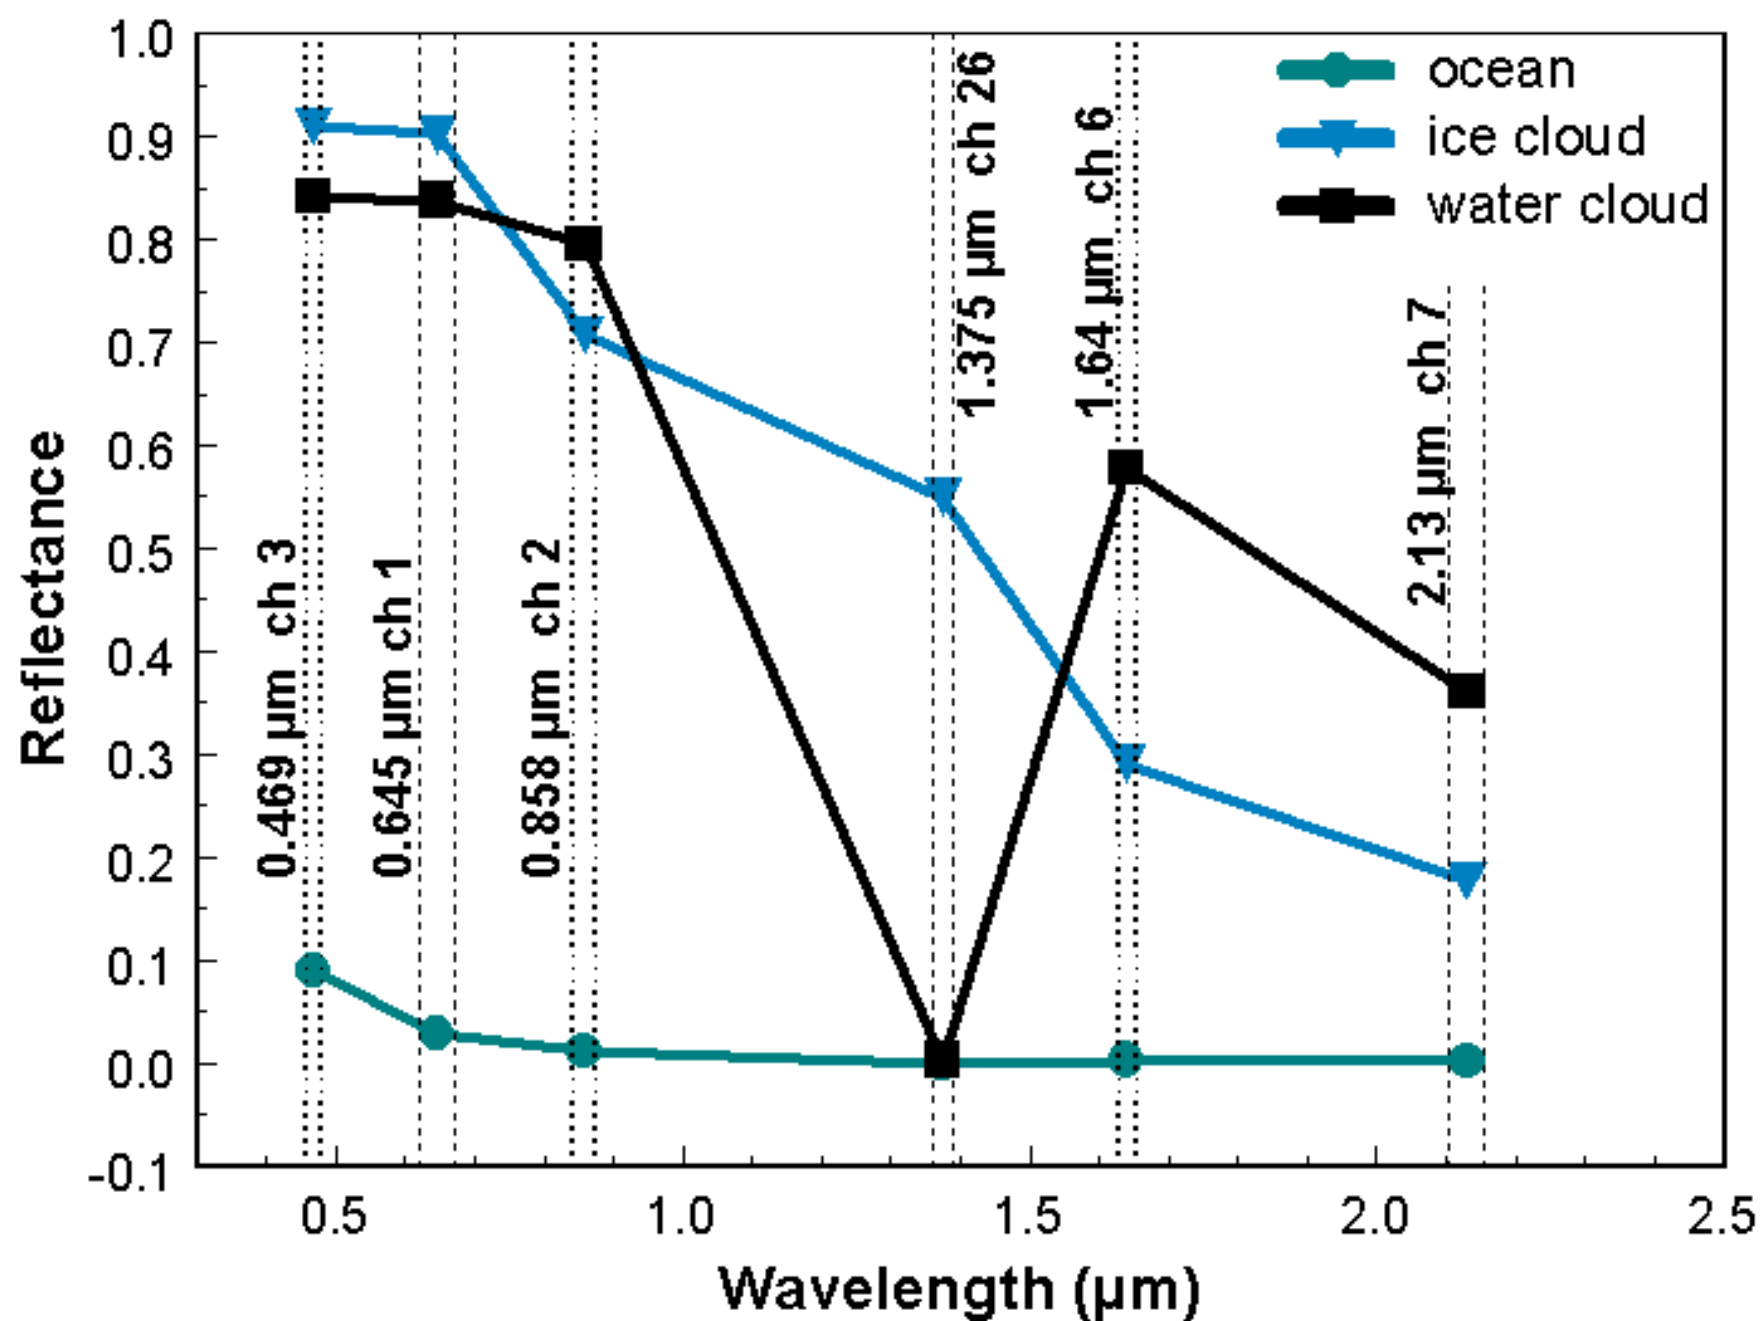

How are they similar?

- They all use at least one visible or near IR channel in which snow is highly reflective (0.4, 0.6, or 0.8 μm)
- They all use at least one channel in which snow is highly absorptive (ie not reflective).
 - MODIS, VIIRS, and SEVIRI products use a near-infrared band (either 1.6 or 2.1 μm)
 - GOES uses the short wave infrared band (3.9 μm)

Visible to Near Infrared

Visible to Near Infrared

SPoRT /NASA RR /CIMSS False Color Snow

**CIMSS /NASA RR
False Color**

CIRA GOES based Cloud and Snow

CIRA / NRL MODIS based Cloud Layers and Snow

CIRA GOES based Cloud and Snow

R: VIS albedo, G: 3.9 μm albedo, B: 10.7 μm BT

Feedback?

- Both positive and negative is welcome.
- Some points to keep in mind:
 - Does the product provide enough contrast to distinguish snow from other features?
 - Are some colors better than others (ie because of colorblindness)
 - Is the product consistent?
 - Does it work the same when the snow cover is deep, shallow, very cold, or near melting?
